Introduction

Aerobus is a C++-20 pure header library for general algebra on polynomials, discrete rings and associated structures.

Everything in Aerobus is expressed as types.

We say that again as it is the most fundamental characteristic of Aerobus:

Everything is expressed as types

The library serves two main purposes:

- Express algebra structures and associated operations in type arithmetic, compile-time;
- Provide portable and fast evaluation functions for polynomials.

It is designed to be 'quite easily' extensible.

Given these functions are "generated" at compile time and do not rely on inline assembly, they are actually platform independent, yielding exact same results if processors have same capabilities (such as Fused-Multiply-Add instructions).

1.1 Structures

1.1.1 Predefined discrete euclidean domains

Aerobus predefines several simple euclidean domains, such as :

```
aerobus::i32: integers (32 bits)
aerobus::i64: integers (64 bits)
aerobus::zpz: integers modulo p (prime number) on 32 bits
```

All these types represent the Ring, meaning the algebraic structure. They have a nested type val < i > where i is a scalar native value (int32_t or int64_t) to represent actual values in the ring. They have the following "operations", required by the IsEuclideanDomain concept :

2 Introduction

- add_t : a type (specialization of val), representing addition between two values
- sub_t : a type (specialization of val), representing subtraction between two values
- mul_t : a type (specialization of val), representing multiplication between two values
- div_t : a type (specialization of val), representing division between two values
- mod_t : a type (specialization of val), representing modulus between two values

and the following "elements":

- one : the neutral element for multiplication, val<1>
- zero : the neutral element for addition, val<0>

1.1.2 Polynomials

Aerobus defines polynomials as a variadic template structure, with coefficient in an arbitrary discrete euclidean domain. As i32 or i64, they are given same operations and elements, which make them a euclidean domain by themselves. Similarly, aerobus::polynomial represents the algebraic structure, actual values are in aerobus::polynomial::val.

```
In addition, values have an evaluation function:
```

```
template<typename valueRing> static constexpr valueRing eval(const valueRing& x) {...}
```

Which can be used at compile time (constexpr evaluation) or runtime.

1.1.3 Known polynomials

```
Aerobus predefines some well known families of polynomials, such as Hermite or Bernstein: using B23 = aerobus::known_polynomials::bernstein<2, 3>; // 3X^2(1-X) constexpr float x = B32::eval(2.0F); // -12
```

They have their coefficients either in aerobus::i64 or aerobus::q64. Complete list is (but is meant to be extended):

- chebyshev_T
- chebyshev_U
- laguerre
- hermite_prob
- hermite_phys
- bernstein
- · legendre
- bernoulli

1.1 Structures 3

1.1.4 Conway polynomials

When the tag AEROBUS_CONWAY_IMPORTS is defined at compile time (-DAEROBUS_CONWAY_IMPORTS), aerobus provides definition for all Conway polynomials CP(p, n) for p up to 997 and low values for n (usually less than 10).

```
They can be used to construct finite fields of order p^n ( \mathbb{F}_{p^n}): using F2 = zpz<2>; using PF2 = polynomial<F2>; using F4 = Quotient<PF2, ConwayPolynomial<2, 2>::type>;
```

1.1.5 Taylor series

Aerobus provides definition for Taylor expansion of known functions. They are all templates in two parameters, degree of expansion (size_t) and Integers (typename). Coefficients then live in Fraction Field < Integers >.

They can be used and evaluated:

Exposed functions are:

- exp
- expm1 $e^x 1$
- lnp1 $(\ln(x+1))$
- geom $(\frac{1}{1-x})$
- sin
- cos
- tan
- sh
- cosh
- tanh
- asin
- acos
- acosh
- asinh
- atanh

Having the capacity of specifying the degree is very important, as users may use other formats than float64 or float32 which require higher or lower degree to achieve correct or acceptable precision.

It's possible to define Taylor expansion by implementing a $coeff_at$ structure which must meet the following requirement:

4 Introduction

- Being template in Integers (typename) and index (size_t);
- Exposing a type alias type, some specialization of FractionField<Integers>::val.

For example, to define the serie $1+x+x^2+x^3+\ldots$, users may write:

```
template<typename Integers, size_t i>
struct my_coeff_at {
    using type = typename FractionField<Integers>::one;
};

template<typename Integers, size_t degree>
    using my_serie = taylor<Integers, my_coeff_at, degree>;

static constexpr double x = my_serie<i64, 3>::eval(3.0);
```

On x86-64 and CUDA platforms at least, using proper compiler directives, these functions yield very performant assembly, similar or better than standard library implementation in fast math. For example, this code:

```
double compute_expm1(const size_t N, double* in, double* out) {
   using V = aerobus::expm1<aerobus::i64, 13>;
   for (size_t i = 0; i < N; ++i) {
      out[i] = V::eval(in[i]);
   }
}</pre>
```

Yields this assembly (clang 17, -mavx2 -03) where we can see a pile of Fused-Multiply-Add vector instructions, generated because we unrolled completely the Horner evaluation loop:

```
compute_expm1(unsigned long, double const*, double*):

1.2 Operations

1.2.1 Field of fractions

Given a set (type) satisfies the IsEuclideanDomain concept, Aerobus allows to define its field of fractions.

1.3 Misc 5

This new type is again a euclidean domain, especially a field, and therefore we can define polynomials over it.

For example, integers modulo p is not a field when p is not prime. We then can define its field of fraction and polynomials over it this way:

```
using namespace aerobus;
using ZmZ = zpz<8>;
using Fzmz = FractionField<ZmZ>;
using Pfzmz = polynomial<Fzmz>;
```

The same operation would stand for any set that users would have implemented in place of ZmZ.

For example, we can easily define rational functions by taking the ring of fractions of polynomials: using namespace aerobus; using RF64 = FractionField<polynomial<q64>>;

Which also have an evaluation function, as polynomial do.

1.2.2 Quotient

Given a ring R, Aerobus provides automatic implementation for $\ \, \text{quotient ring } R/X \ \, \text{where X is a principal}$ ideal generated by some element, as we know this kind of ideal is two-sided as long as R is commutative (and we assume it is).

```
For example, if we want R to be \mathbb{Z} represented as aerobus::i64, we can express arithmetic modulo 17 using: using namespace aerobus; using \text{ZpZ} = \text{Quotient} < \text{i64}, i64::val<17>>;
```

As we could have using zpz < 17 >.

This is mainly used to define finite fields of order p^n using Conway polynomials but may have other applications.

1.3 Misc

1.3.1 Continued Fractions

```
Aerobus gives an implementation for continued fractions. It can be used this way: using namespace aerobus; using T = ContinuedFraction<1,2,3,4>; constexpr double x = T::val;
```

```
As practical examples, aerobus gives continued fractions of \pi, e, \sqrt{2} and \sqrt{3}: constexpr double A_SQRT3 = aerobus::SQRT3_fraction::val; // 1.7320508075688772935
```
